Kurzbeschreibung:	Wildfires are becoming more and more a common phenomenon, due to climate change. Lidar systems are ideal for observing smoke layers in the upper troposphere/lower stratosphere (UTLS) and studying their evolution. PollyXT lidar systems have been deployed all over the world, thus, capturing several large wildfire events e.g., the Australian wildfire, the Californian wildfires, etc. The optical and microphysical properties of smoke are highly variable, depending on the burned vegetation type, location, fire type (smoldering or flaming combustion), altitude, and the age of the smoke particles. In the scope of the thesis, case studies from different wildfire events, with a specific focus on European and North American events, will be analyzed in detail in terms of optical properties. An intercomparison between the case studies is also foreseen to identify the differences in the optical properties of the smoke particles and potentially reveal the reason for the differences.
